Abstract In this study, the numerical investigation of Al_2O_3-Water nanofluid mixed convection in a T-shaped lid-driven cavity in the presence of a thermal barrier with positioning at different positions is investigated by the two-phase mixture model. Variable parameters in this study are the cavity aspect ratio (AR), the volume fraction of nanoparticles (ϕ), Richardson numbers (Ri), and different thermal barrier placements in the cavity. The results indicated that the increase in the Richardson number leads to an increase in the local and average Nusselt number (Nu_{ave}) and heat transfer. Increasing the ϕ also increases the heat transfer while increasing the aspect ratio decreases the heat transfer. Regarding the geometrical position of the thermal barrier, the results show that the geometrical position of the thermal barrier near the lid has the highest heat transfer and the Nusselt number. Numerical investigation of nanofluid mixed convection in a T-shaped cavity by considering a thermal barrier is the originality of this work.

1. Introduction

Nanostructures are very important in many applications of engineering, technology and natural processes [1–6]; among

Nomenclature

$\vec{V}$	velocity [m/s]		ρ	density [kg/m^3]
g	gravity [m/s^2]		β	thermal expansion coefficient [1/K]
T	temperature [K]		μ	viscosity [Pa.s]
AR	aspect ratio			
L	length [m]		*Abbreviations*	
k	thermal conductivity [W/m.K]		f	fluid
Nu	Nusselt number		p	particle
Gr	Grashof number		eff	effective
Ri	Richardson number		h	hot
f$_{drag}$	drag function		c	cold
X	dimensionless longitudinal component		loc	local
Y	dimensionless transverse component		ave	average
x	longitudinal component [m]		m	mixture
y	transverse component [m]		k	kth phase
			lid	lid-driven
Greek symbols			dr	drift
ϕ	volume fraction			

these applications, these applications include cooling systems that are used today in industries such as power generation, transportation and electronics. Nanofluids can be used to achieve greater heat transfer [7–17]. In recent decades, a lot of research was done on nanofluids [18], MEMS [19], and structural, morphological and optical properties of nanosttructures [20–23]. Their research showed that the Richardson number was the cause of the increase in heat transfer. Mirmasoumi and Behzadmehr [24] investigated the heat transfer of nanofluid in a cavity. They showed that the convective heat transfer coefficient increases with decreasing nanoparticle's diameter. Aminossadati and Ghasemi [25] conducted a numerical study of mixed convection in an open cavity. They proved that in low Richardson numbers, the streamlines are not drawn into the cavity, and in the high Richardson numbers, the streamlines are inclined inward and contain vortices. Wong and Saeid [26] studied the mixed convection around the cooling jet inside the open cavity. They found that Nu_{ave} increased with increasing Péclet number and decreasing the depth of the cavity. Abu-Nada and Chamkha [27] studied the mixed convection of a nanofluid in an inclined cavity, numerically. Their cavity was square-shaped, and its upper and lower walls were exposed to hot and cold temperatures, respectively. They used water-alumina nanofluid. They found that the heat transfer coefficient increased significantly in the presence of nanoparticles. Mahmoudi et al. [28] conducted a numerical study of free convection in an open cavity with two hot sources attached to horizontal walls. They concluded that the streamlines and the isotherm lines were highly dependent on Rayleigh numbers and the distance between the hot sources. In a study of the combined effect of Joule heating and hydrodynamic magnetism, Rahman et al. [29] showed that as the aspect ratio increases, the Nusselt number decreases, the Sherwood increases, and the temperature function remains almost constant. Barnoon et al. [30] studied mixed convection heat transfer of a nanofluid in a porous enclosure. In their work, the enclosure was equipped with rotating circular cylinders and filled. They examined the heat transfer using LTE and LTNE

models. They found that the use of rotating cylinders could play an amazing role in improving heat transfer. The same author investigated the effect of heat transfer on the destruction of the gland in biological tissue [31]. Using intense heating, it was shown that tissue can be easily destroyed. Mahmoodi [32] studied the free convection of water-copper nanofluids with a finite volume method in an "L-shaped" cavity. He found that in all aspect ratios, the average Nusselt number improves with increasing Rayleigh number and volume fraction of nanoparticles. Mahmoudi et al. [33] examined the effect of a baffle movement on the convective heat transfer in a channel with heating components. The increase in baffle height at different Richardson numbers is not so great. Parvin and Nasrin [34], similar to Mojumder et al. [35] examined a cavity containing a hot cylindrical piece. They showed that increasing the Reynolds number caused the Nusselt number to increase. Sebdani et al. [36] investigated the mixed convection of water-alumina nanofluid in a square cavity. The left and right walls of the cavity were exposed to cold temperatures and had a constant velocity. The other walls were insulated and only part of the lower wall was exposed to hot temperature. They concluded that as the heat source moves toward the sidewall, the heat transfer rate also increases. Parvin et al. [37] studied the impacts of Soret and Dufour coefficients on natural convection flow phenomena in a partially heated square cavity saturated with water-alumina nanofluid. The upper and lower walls of the cavity were exposed to hot and cold temperatures, respectively, and the other walls were insulated. They found that that both heat and mass transfer were increased by Soret and Dufour coefficients. Sheikhzadeh et al. [38] investigated the free convection in a square cavity with a central heat source. They found that in the studied geometries, as the Rayleigh number increased, the boundary layer became thinner and the heat transfer improved. Mansour et al. [39] investigated the free convection of fluid flow and heat transfer in a "T-shaped" cavity containing a water-Copper nanofluid numerically. The results showed that Nu_{ave} increased with increasing Rayleigh number and ϕ. Abbasian et al. [40]

examined free convection in a sloping "L-shaped" cavity containing a water-copper nanofluid. Their results showed that a decrease in the shape factor and an increase in ϕ led to an increase in Nu_{ave}. Sheikholeslami et al. [41] investigated the free convection of a nanofluid in a cavity. The results showed that Nu_{ave} decreased with increasing the Buoyancy force. Bakier [42] studied the numerical free convection in an open C-shaped cavity containing nanofluid along with a hot source on the cavity wall and found that the density of streamlines and isotherm lines at the top of the cavity was higher. Nasrin and Alim [43] talked about free convection in a closed cavity filled with nanofluids. Their results show that the size of the largest and smallest vortices between the horizontal wall and the hot obstacle did not differ much. Esfe et al. [44] studied the mixed convection in a cavity containing a water-alumina nanofluid with a hot internal source. They found that Nu_{ave} for all ϕ increases with decreasing Richardson number. Further studies on heat transfer within T-shaped cavities in Refs. [52–54] are recommended. In Ref. [52–54], there was only one T-shaped cavity (without thermal barrier) to which a magnetic field was applied and a single-phase nanofluid flowed through it. However, the effect of the magnetic field was considered as a negative factor. Fluid flow and nanofluid heat transfer in cavities using new mechanisms are introduced as valuable numerical studies [55–60]. Also, These mechanisms can be merged with other nanostructures in Refs. [49–51].

A review of the literature shows strong studies on the heat transfer of nanofluids within cavities. However, heat transfer in the T-shaped cavity has received less attention. This study investigates fluid flow and heat transfer in a T-shaped cavity using a thermal barrier. The thermal barrier is placed in different places inside the cavity to achieve the best heat transfer rate. Different aspect ratios are investigated to achieve the best heat transfer rate using a two-phase model.

2. Problem statement and governing equations

2.1. Definition of the problem

The geometry studied in this study is a T-shaped lid-driven cavity and a thermal barrier. The studied cavity is examined in different aspect ratios of AR = 0.2, 0.3, and 0.4, as well as the different positions of the thermal barrier in the cavity. The lid of the cavity moves from left to right at the velocity of V_{lid} and is located at a temperature of 300 K. All walls of the cavity, except for the thermal barrier walls, are considered adiabatic, and the thermal barrier walls are at a constant temperature above the cover temperature. The temperature difference between the thermal barrier walls and the cover is determined by Ri = 0.1, 1, and 10. The schematic of the problem is shown in Fig. 1. The driving force in the geometry under study is the high velocity of the lid and the buoyancy force due to the temperature difference between the thermal barrier and the moving lid. This flow is considered to be the incompressible water-alumina nanofluid in ϕ = 0, 1, 2, and 3 % inside a cavity. The Newtonian base fluid is assumed, and density changes are considered in such a way that the motion factor can be quickly attributed to the moving lid and the density changes. Any heat effect from the pressure field is ignored. Mixed convection in the cavity includes natural convection due to constant temperature wall temperature differences and forced convection due to lid movement.

Also, the information about the present problem is presented in Table 1.

2.2. Mixture two-phase model

Continuity equation [45]:

$$\vec{\nabla}.\left(\rho_m \vec{V}_m\right) = 0 \tag{1}$$

Momentum equation [45]:

$$\vec{\nabla}.\left(\rho_m \vec{V}_m \vec{V}_m\right) = -\vec{\nabla}P + \vec{\nabla}.\left[\mu_m\left(\vec{\nabla}\vec{V}_m + \vec{\nabla}\vec{V}_m^T\right)\right] + \rho_m \vec{g} + \vec{F} - \vec{\nabla}.\left(\sum_{k=1}^{n}\phi_k\rho_k \vec{V}_{dr,k} \vec{V}_{dr,k}\right) \tag{2}$$

The k subscript represents the number of phases distributed in the base fluid. In this part, k = 1 and the third statement in Equation (2) are defined as follows [45],

$$\vec{\nabla}.\left(\sum_{k=1}^{n}\phi_k\rho_k \vec{V}_{dr,k} \vec{V}_{dr,k}\right) = \vec{\nabla}.\left(\phi_p\rho_p \vec{V}_{dr,p} \vec{V}_{dr,p}\right) \tag{3}$$

Energy equation [28]:

$$\vec{\nabla}.\left(\sum_{k=1}^{n}(\rho_k c_k)\phi_k \vec{V}_k T\right) = \vec{\nabla}.\left(k_{eff}T\right) \tag{4}$$

The equation for the volume ratio of particles is defined as follows:

$$\vec{\nabla}.\left(\phi_p\rho_p \vec{V}_m\right) = -\vec{\nabla}.\left(\phi_p\rho_p \vec{V}_{dr,p}\right) \tag{5}$$

In the equations presented, the parameters are defined as follows:

$$\vec{V}_m = \frac{\sum_{k=1}^{n}\phi_k\rho_k \vec{V}_k}{\rho_{eff}} \tag{6}$$

$$\vec{\tau} = \mu_{eff}\vec{\nabla}V_m \tag{7}$$

In Eq. (3), $\vec{V}_{dr,k}$ is the buoyancy velocity for the second phase is defined as the difference between the nanoparticle velocity and the mixture velocity,

$$\vec{V}_{dr,k} = \vec{V}_k - \vec{V}_m \tag{8}$$

Relative velocity is defined as the difference between the velocity of the second phase (nanoparticles) and the velocity of the first phase (base fluid):

$$\vec{V}_{pf} = \vec{V}_p - \vec{V}_f \tag{9}$$

and

$$\vec{V}_{dr,p} = \vec{V}_{pf} - \sum_{k=1}^{n}\frac{\phi_k\rho_k}{\rho_{eff}}\vec{V}_{fk} \tag{10}$$

In Eq. (10), the drag function is represented as follows [45],

$$\vec{V}_{pf} = \frac{\rho_p d_p^2}{18\mu_f f_{drag}}\frac{(\rho_p - \rho_{eff})}{\rho_p}\vec{a} \tag{11}$$

Fig. 1   Schematic of the problem.

3	1	100	10	22.725	0.00849
3	10	100	3.16	22.725	0.00268

$$f_{drag} = \begin{cases} 1 + 0.15Re_p^{0.687} \; Re_p \leqslant 1000 \\ 0.15Re_p \; Re_p > 1000 \end{cases} \quad (12)$$

$\overrightarrow{a}$ in Equation (11) is defined as follows [45],

$$\overrightarrow{a} = \overrightarrow{g} - \left(\overrightarrow{V}_m . \overrightarrow{\nabla} \right) \overrightarrow{V}_m \quad (13)$$

The relationships used to calculate the effective properties of nanofluid are as follows:

Effective density:

$$\rho_{eff} = (1 - \phi)\rho_f + \phi\rho_p \quad (14)$$

Effective thermal expansion coefficient [46]

$$\beta_{eff} = \left[\frac{1}{1 + \frac{(1-\phi)\rho_f}{\phi\rho_p}} \frac{\beta_p}{\beta_f} + \frac{1}{1 + \frac{\phi}{(1-\phi)}\frac{\rho_p}{\rho_f}} \right] . \beta_f \quad (15)$$

Effective viscosity [47],

$$\mu_{eff} = \frac{\mu_f}{(1 - \phi)^{0.25}} \quad (16)$$

Effective thermal conductivity [46],

$$\frac{k_{eff}}{k_f} = \frac{k_p + 2k_f - 2\phi(k_f - k_p)}{k_p + 2k_f + \phi(k_f - k_p)} \quad (17)$$

The properties calculated for the nanofluid are also given in Table 2.

The local Nusselt number along the hot wall can be obtained by the following formula:

$$Nu_{loc} = \frac{\frac{\partial T}{\partial n} L}{T_h - T_c} \quad (18)$$

The average Nusselt number along the cavity is calculated as follows:

$$Nu_{ave} = \frac{1}{L*} \int_0^{L*} Nu_{loc} (dL*) \quad (20)$$

Richardson, Grashof, and Reynolds numbers for nanofluids are defined as follows:

$$Ri = \frac{Gr}{Re^2}, \quad Gr = \frac{\rho_{eff}^2 g\beta_{eff}\Delta TL^3}{\mu_{eff}^2}, \quad Re = \frac{\rho_{eff}V_{lid}L}{\mu_{eff}} \quad (21)$$

The dimensionless length of the thermal barrier, aspect ratio, and other dimensionless numbers of the problem are also given below,

$$L_1 + L_2 + L_3 = L* \quad (22)$$

$$\frac{Lenght}{L*} = L**$$

$$AR = l/L$$

**Fig. 2** Validation diagram.

$$\Delta T = T_h - T_c$$

$$Y* = \frac{y}{L}$$

$$X* = \frac{x}{L}$$

2.3. Methods and boundary conditions

In this research, for simulation, the steady two-dimensional method was studied with double-precision. The solver type in this study is pressure-based, which has been used to link the velocity and pressure. Also, for discrete equations, the second-order UPWIND method is used. A convergence criterion in this paper for all residues is 10^{-6} for all equations [32–34]. The boundary conditions used in this study are:

- The constant temperature on thermal barrier walls
- A constant temperature of 300 K on the lid
- Fixed velocity corresponding to Richardson number for the lid

Fig. 3 The Nu_{ave} versus the number of computational grids in Ri = 0.1, ϕ = 3%, and AR = 0.2 for case.

Fig. 4   An example of the computational grid used in this study.

- Other walls are considered adiabatic.
- The gravitational acceleration is equal to 9.81 m /s^2, and the working pressure is equal to 1 atm.
- Properties are independent of temperature and are only a function of ϕ.
- The Boussinesq approximation has been used to investigate the effect of temperature on fluid density difference.

$$cold\,wall\,V_m = V_{m,x}, T = T_c \tag{23}$$

$$hot\,wall\,V_{m,x} = V_{m,y} = 0, T = T_h$$

$$other\,walls\,V_{m,x} = V_{m,y} = 0, \frac{\partial T}{\partial x} = \frac{\partial T}{\partial y} = 0$$

2.4. Validation, grid computing, and grid independency

To ensure the accuracy of the results of the present study simulation, the method used in this study is compared with Alinia et al. [48]. They investigated the mixed convection of a nanofluid in a square cavity in the Richardson number range is 0. 01 < Ri < 100 using a two-phase mixture method. Because the range of Richardson numbers in the present study is 0.1 < Ri < 10, the results were compared in Ri = 0.1, 1, and 10. As can be seen in Fig. 2, the results are well overlapped. The difference in results in most cases is < 1.5%. Given that the error below 3% is generally acceptable for comparison with numerical tasks, these results are quite acceptable.

This study uses a uniformly structured computational grid. Also, to grid independency, the Nu_{ave} in Ri = 0.1, ϕ = 3%, and the case a in AR = 0.2 have been investigated. Therefore, to investigate and compare this parameter, the results of five computational grids have been compared and shown in Fig. 3. Fig. 3 shows the graph of the Nu_{ave} versus the number of computational grids in Ri = 0.1, ϕ = 3 %, and AR = 0.2 for case a. As can be seen from step 3, Nu_{ave} changes from very small to very small, so that the error rate drops below 3 %. As a result, 250,000 cells will be used in the research, and the

computational grid will be optimal. An example of the computational grid used in this study is also shown in Fig. 4.

3. Results and discussion

3.1. Effect of Richardson number on hydrodynamic and thermal parameters

3.1.1. The local Nusselt number

Fig. 5 shows a diagram of Nu_{loc} versus dimensionless length in Ri = 0.1, 1 and 10, AR = 0.2, 0.3 and 0.4, and cases a, b, and c in ϕ = 1 %. The Nu_{loc} is calculated on the thermal barrier. Since the three sides of the thermal barrier are related to the fluid, it can be seen that in all diagrams, the Nu_{loc} graph is divided into three sections with three different behaviors. Each section corresponds to one side of the barrier. Based on the figures, it can be seen that in all cases, as the Richardson number increases, the overall level of the Nu_{loc} decreases, so that the highest Nusselt number is related to the Ri = 0.1 and the lowest is related to Ri = 10. The reason for this can be better understood by considering the Richardson number formula. As Richardson number increases, the velocity of the lid decreases, and as a result, the intensity of the secondary flow created also decreases. In other words, with the increase in Richardson number, the rate of forced convection decreases, and the share of natural convection increases.

3.1.2. Average Nusselt number

Fig. 6 shows the Nu_{ave} versus Richardson number in AR = 0.2, 0.3 and 0.4, ϕ = 0, 1, 2 and 3%, the geometric cases a, b and c, and Ri = 0.1, 1 and 10. As can be seen, the relationship between the Nu_{ave} and the Richardson number is reversed, so that with the increase in Richardson numbers, the Nu_{ave} decreases. The reason is the decrease in the share of heat transfer of forced convection and the dominance of free convection over forced convection. For case a, and AR = 0.2, the rate of decrease in the Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 in ϕ = 0% is 36.34 and 79.98%, respectively. The rate of these reductions in ϕ = 1% was 34.12% and 80.47%, respectively; in ϕ = 2% equal to 33.85 and 80.93% and in

$\phi = 3\%$ equal to 33. 38 and 81.19 %. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1 and $\phi = 3\%$, which is equal to 4.87 and the lowest Nu_{ave} is related to Ri = 10, which is equal to 2.58. For case a and AR = 0.3, the rates of decrease in the Nu_{ave} in Ri = 1 and 10 compared to Ri = 0.1 in $\phi = 0\%$ are 22.3 and 50.27%, respectively. The values of these reductions in $\phi = 1\%$ are equal to 22.06 and 50.52%, in $\phi = 2\%$ are equal to 21.69 and 50.66% and in $\phi = 3\%$ are equal to 21.34 and 50.87%. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1, and $\phi = 3\%$, which is equal to 3.18, and the lowest Nu_{ave} is related to Ri = 10, and $\phi = 0\%$ which is equal to 2.05. For geometric case a and AR = 0.4, the rates of decrease in the Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 in $\phi = 0\%$ are 10.5 and 22.33%, respectively. Decrease in these values in $\phi = 1\%$ equal to 10.37 and 22.46%, in $\phi = 2\%$ equal to 10.19 and 22.56% and in $\phi = 3\%$ equal to 9.94 and 22.62%. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1 and $\phi = 3\%$ which is equal to 1.45 and the lowest Nu_{ave} is related to the Ri = 10 number and $\phi = 0\%$ which is equal to 1.17. For the geometric case b and the AR = 0.2, the rates of decrease in the Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 in $\phi = 0\%$ are equal to 3.87 and 70.96%, respectively. The values of these reductions in the $\phi = 1\%$ are equal to 30.66 and 71.32%, in the $\phi = 2\%$ are equal to 30.43 and 71.63% and in the $\phi = 3\%$ are equal to 30.01 and 71.76 %. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1, and $\phi = 3\%$, which is equal to 4.36, and the lowest Nu_{ave} is related to Ri = 10, and $\phi = 0\%$, which is equal to 2.44. For case b and AR = 0.3, the rates of decrease in the Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 and $\phi = 0\%$ are equal to 22.3% and 50.2%, respectively. The values of these reductions in $\phi = 1\%$ are equal to 22.06% and 50.47%. In $\phi = 2\%$ these reductions are equal to 21.79% and 50.71% and in $\phi = 3\%$ these reductions are equal to 21.4% and 50.8%. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1 and $\phi = 3\%$, which is equal to 3.19, and the lowest Nu_{ave} is related to Ri = 10, and $\phi = 0\%$ which is equal to 2.06. For case b and AR = 0.4, the decrease in the Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 in $\phi = 0\%$ is 12.32% and 26.23%, respectively. The values of these reductions in $\phi = 1\%$ are equal to 12.17% and 26.38%, in $\phi = 2\%$ equal to 11.97% and 26.52% and in $\phi = 3\%$ are equal to 11.69% and 26.61 %. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1 and $\phi = 3\%$, which is equal to 1.72. The lowest Nu_{ave} is related to Ri = 10, and $\phi = 0\%$ which is equal to 1.34. For case c and AR = 0.2, the rates of decrease in Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 in $\phi = 0\%$ are equal to 19.03% and 30.65%, respectively. The values of these reductions in $\phi = 1\%$ are equal to 18.03% and 28.18%, and in $\phi = 2\%$ these reductions are equal to 18.69% and 29.51% and in $\phi = 3\%$ these reductions are equal to 19.38% and 31.04%. It can also be seen that the highest Nu_{ave} is related to Ri = 0.1 and $\phi = 3\%$, which is equal to 11.87, and the lowest Nu_{ave} is related to Ri = 10 which is equal to 9.05. For case c and AR = 0.3, the rates of decrease in the Nu_{ave} in Ri = 1 and 10 compared to the Ri = 0.1 in $\phi = 0\%$ are equal to 17.74% and 27.28%, respectively. The values of these reduc-

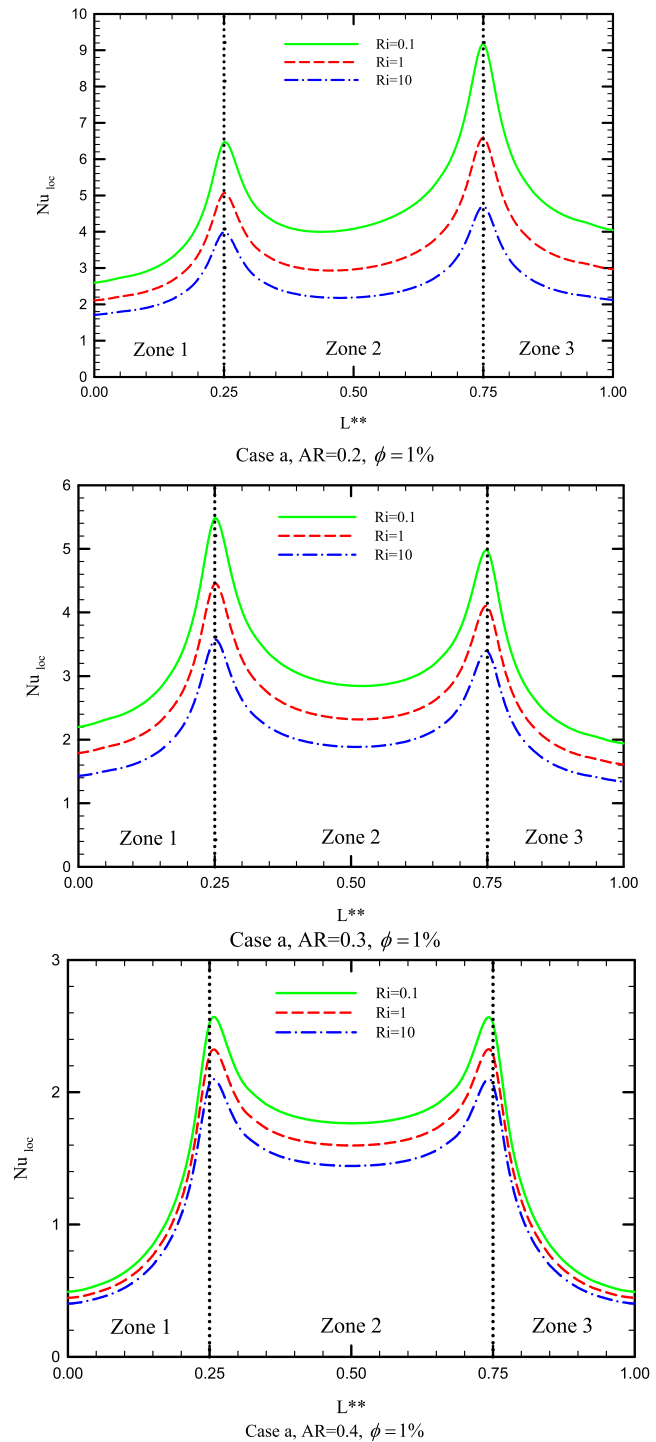

Fig. 5 Nu_{loc} versus dimensionless length.

tions in $\phi = 1\%$ are equal to 18.25 and 28.32%. Average Nusselt number in the case c is far higher than the case b and a because of lid-driven and thermal barrier in close vicinity. Moreover, in case c, when AR grows, Average Nusselt reduces more slowly as Ri number intensifies from Ri = 1 to Ri = 10
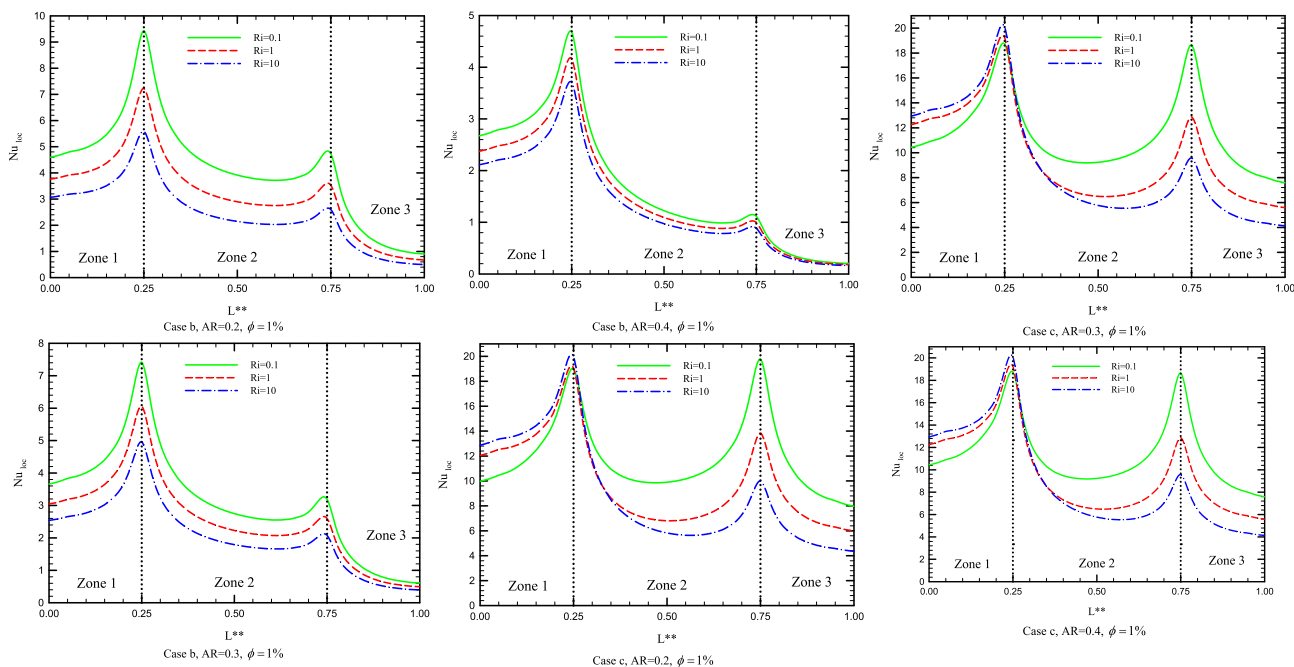

Fig. 5 (*continued*)

**Fig. 6** Nu_{ave} versus Richardson number at a different.

than Ri intensifies from Ri = 0.1 to Ri = 0.1. This is because of thermal barrier position, which is close to the top of the cavity. As the volume fraction increases due to the increased thermal conductivity of the nanofluid, the heat transfer increases in all cases.

3.1.3. Temperature and velocity contours

Fig. 7 shows the temperature distribution contour in case a and AR = 2.0, $\phi = 0\%$, and Ri = 0.1, 1, and 10. As can be seen, the density of the isotherm lines near the thermal barrier is higher in lower Richardson numbers. The higher density of the isotherm lines near the thermal barrier indicates a higher temperature gradient. A higher temperature gradient is also one of the signs of a higher heat transfer rate, which can be

Case b and AR=0.3
Case c and AR=0.2

Fig. 6 (*continued*)   **Fig. 6** (*continued*)

seen in the lower Richardson numbers. It can also be seen that as the Richardson number increases, the isotherm lines become more uniform (horizontally). The reason for this can be described by the fact that with the increase in the Richardson number, the share of heat transfer of forced convection decreases, and the share of heat transfer of free convection increases.

Figs. 8 and 9, respectively, show the velocity distribution contour and velocity vector in geometric case a, AR = 0.4, $\phi = 0\%$, and Ri = 0.1, 1, and 10. As can be seen, the line density in the velocity contour is inversely related to Richardson number so that as Richardson number increases, the line density decreases. The main density of lines in all cases is near the moving lid. As Richardson number increases, the velocity of the moving lid decreases, so the density of the lines, which also indicates the velocity gradient, also decreases. Also, according to Fig. 9, which shows the velocity vector, it can be seen that as the Richardson number increases, the order of magnitude of the velocity vectors decreases at all points. Also, the velocity vectors near the moving lid are more significant than other points.

Figs. 10 and 11 show the streamlines and vorticity contours for case a, in $\phi = 0\%$, AR = 0.2, and Ri = 0.1, 1, and 10. Due to the streamlines, it can be seen that the density of the stream-

lines on the sides of the cavity is higher than the center of the cavity, which indicates more velocity in the parts where the density of the streamlines is higher. The highest density of streamlines is also near the driving lid.

3.1.4. Velocity profile

Fig. 12 shows the velocity profile in the y-direction in the center of the cavity in geometric cases a, b, and c, Ri = 0.1, 1, and 10, $\phi = 1\%$, and AR = 0.2, 0.3, and 0.4. As can be seen, the velocity profile behavior in all cases has a prominent feature, so that by moving from the highest amount of Y* to its lowest level, first the velocity is in its maximum state and then rapidly decreases to 0. This behavior occurs in the range of 0.75 < Y* < 1. Then, as the amount of Y* decreases, the value of the velocity increases again, but in the negative direction, and by reaching another maximum value, it decreases again and tends to zero, which is the same point Y* = 0. Therefore, it can be concluded that the behavior of the velocity profile is divided into two main parts (in AR = 0.2). The first part is approximately 0 < Y* < 0.75, and the second part is approximately 0.75 < Y* < 1. The reason for this can be attributed to fluid circulation in the first part. In the second part, the movement of the moving lid has affected the fluid layers around it.
Case c and AR=0.3
Case c and AR=0.4

**Fig. 6** (*continued*)

Ri=0.1

Ri=1

Another point that can be mentioned is the slope of the velocity profile chart; so that, with the increase of Richardson number, the velocity profile becomes flatter, which can be attributed to the decrease in lid's velocity, which also leads to a reduction in circulation. Therefore, with the increase in the Richardson number, the amount of velocity in both areas decreases.

3.2. Investigating the effect of aspect ratio

3.2.1. Check the velocity and temperature contours

Fig. 13 shows the velocity contour in case a, Ri = 0.1, ϕ = 0%, and AR = 0.2, 0.3, and 0.4. As can be seen, by increasing the aspect ratio, the density of the streamlines distances from the thermal barrier. In other words, in smaller aspect ratios, the line's density is also higher near the thermal barrier, and this density decreases with increasing aspect ratio. Since one of the factors in increasing heat transfer is the increase in velocity gradient on the thermal barrier walls and by considering that the higher density of velocity lines indicates a higher velocity gradient, so we can see the reduction of velocity gradient on the thermal by an increase in the aspect ratio.

Figs. 14 and 15, respectively, show the stream and vorticity lines for case a in ϕ = 0%, Ri = 0.1 and AR = 0.2, 0.3 and 0.4, respectively. As can be seen, unlike Richardson number's

Ri=10
**Fig. 7**   Isotherm contours in case a and ϕ = 0%, AR = 0.2.

changes, which had little effect on the stream line's behavior, the changes in the aspect ratio had a significant effect on the streamlines; so that, as the aspect ratio increased, the circulating area became smaller and eventually at AR = 0.4, another circulating area is created in the lower space of the cavity, which has a very low velocity. Also, by increasing the aspect
**Fig. 8** Cantour of velocity distribution in case a and $\phi = 0\%$, AR = 0.2.

Case b and AR=0.2

Fig. 12 (*continued*)

ratio, the circulation area is directed towards the upper wall of the cavity and also stretches along the x-axis.

Fig. 16 shows the contour of the isotherm lines in case a, $\phi = 0\%$, Ri = 0.1 and AR = 0.2, 0.3, and 0.4. As can be seen, as the aspect ratio increases, the density of the isotherm lines decreases near the thermal barrier, indicating a decrease in temperature gradient and a decrease in heat transfer. The reason for this can be described as the fact that by increasing the aspect ratio, does not only the circulation in the vicinity of the thermal barrier decrease, but also the fluid range around the thermal barrier decreases. This reduction causes the surrounding fluid to lose its heat-cooling potential.

3.2.2. Local Nusselt number

Fig. 17 shows a diagram of the local Nusselt number in terms of dimensionless length L** for geometric cases a, b and c, AR = 0.2, 0.3, and 0.4, in $\phi = 1\%$ and Ri = 0. 1. As can

be seen, in geometric cases a and b, as the aspect ratio increases, the overall level of the local Nusselt number chart on all sides of the thermal barrier decreases, but this is not the case in case c, and the Nusselt number increases in some areas with increasing aspect ratio and reduced in others. As explained, the reason for this is related to the distance of the thermal barrier to the lid as well as the more limited circulation area.

Fig. 18 shows the Nu_{ave} versus AR in Ri = 0.1, 1, and 10, $\phi = 0$, 1, 2, and 3 %, for the geometric case a. As can be seen, in case a, increasing the aspect ratio in all Richardson numbers and ϕ leads to a decrease in the Nu_{ave}. In all cases, the highest Nu_{ave} is related to the lowest Richardson number and the lowest aspect ratio, and the highest Nu_{ave} is related to the highest Richardson number and the highest aspect ratio. In $\phi = 0\%$, the values of the Nu_{ave} in Ri = 0.1 and in AR = 0.2, 0.3,

and 11.8. These values in Ri = 1 are equal to 9.94, 9.9 and 9.83, and in Ri = 10 are equal to 9.05, 9.03 and 8.97. The rate of decrease in the Nu_{ave} in AR = 0.3 and 0.4 compared to AR = 0.2 and Ri = 0.16 and 0.6%, respectively. These values in Ri = 1 are equal to 0.35 and 1.13 and in Ri = 10 are 0.31 and 0.9 %.

4. Conclusion

In this study, the numerical simulation of mixed convection of water-aluminum oxide nanofluid in a T-shaped lid-driven cavity was investigated in the presence of a thermal barrier located in different positions of the cavity using the two-phase mixture method. This study included Ri = 0.1, 1 and 10, ϕ = 0, 1, 2 and 3 %, AR = AR = 0.2, 0.3 and 0.4. Also, three different positions for the thermal barrier were checked.

- Increasing the Richardson number reduces the heat transfer rate due to the reduction of secondary flows through the moving lid.
- Increasing the ϕ increases in heat transfer.
- Increasing the aspect ratio of the cavity reduces the heat transfer.
- The reduction in heat transfer rate is greater due to the increase in the aspect ratio of the abacus in cases a and b than in case c because the circulation caused by the secondary flow created by the lid in the vicinity of the thermal barrier is more limited.
- Case c has a higher heat transfer than in cases a and b, which can be attributed to the fact that it is adjacent to the driving lid.
